Research and teaching institute for ultrafine bioresonance therapy (BRT) and test methods

Biophysical allergy therapy

Extract from a study by Dr P. Schumacher, paediatrician, Innsbruck:

At a time when allergies are becoming increasingly significant throughout the world and billions are being spent on allergy research every year, the claim that allergies could be cured sounds extremely provocative.

However, bioresonance therapy is in fact capable of not only treating but completely eliminating allergies!

An example:

The photographs show an example of a treated milk allergy

Allergy as a phenomenon of biophysical information

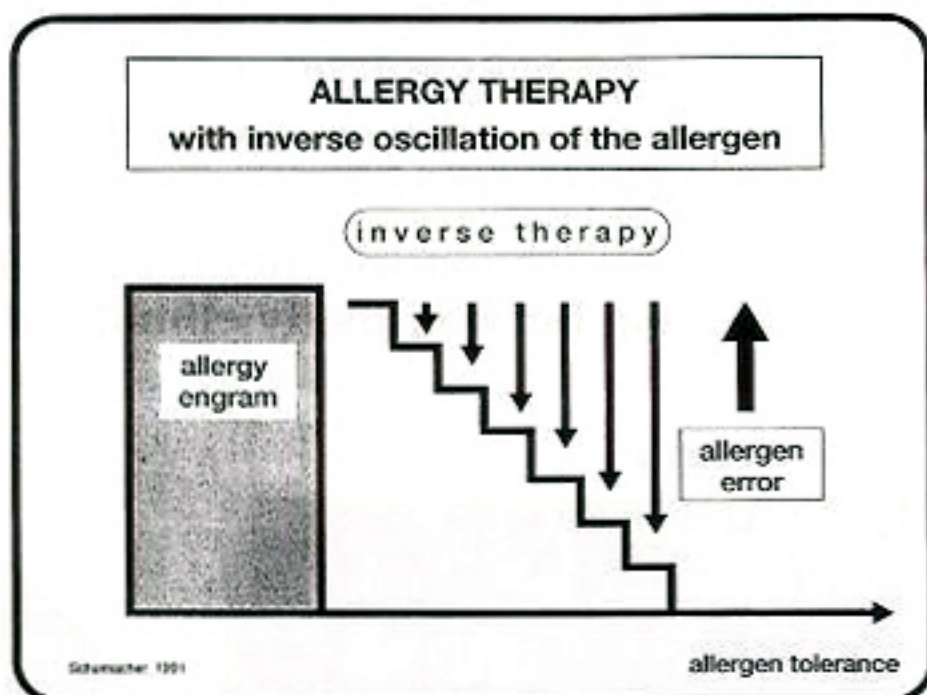

It has long been known that allergic reactions can be triggered by unimaginably small quantities of the allergen in highly sensitive persons (e.g. anaphylactic shock of a patient with milk allergy on entering a room in which milk has been heated). Professor C. Smith was able to prove on the basis of numerous scientifically precisely conducted experiments that in

hyperergically reacting subjects not just the allergenic substance itself but also its homeopathic preparations down to the range of high and very high potencies which are certainly free of matter are effective, and that even specific electric frequencies alone may be sufficient to trigger very severe allergic reactions.

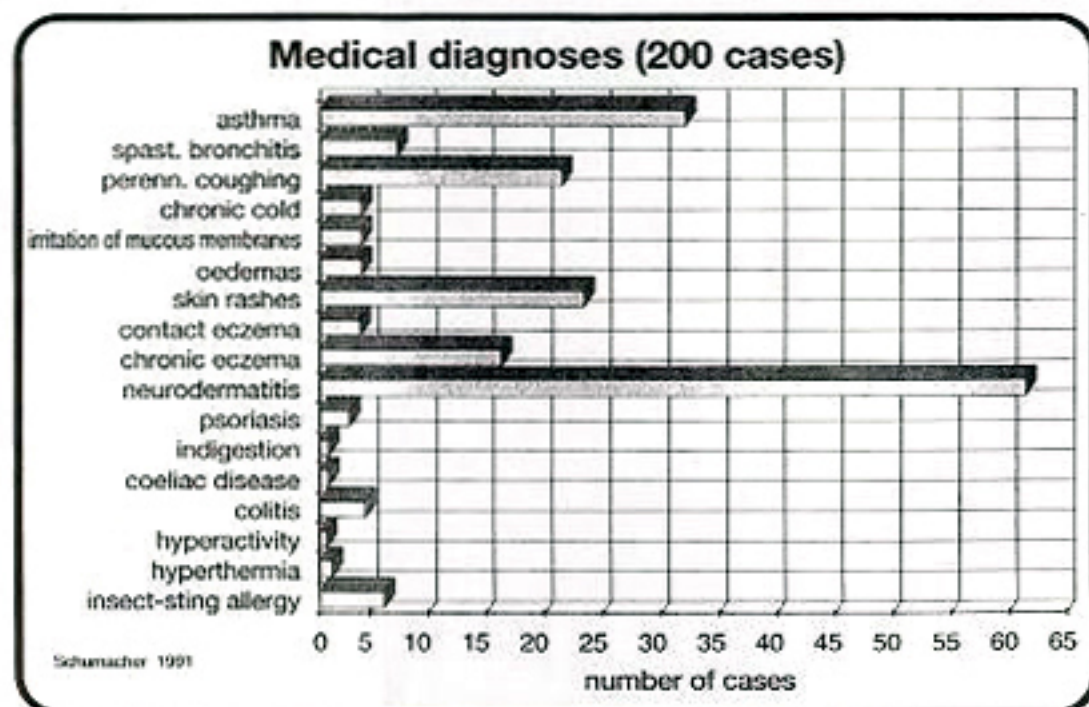

It is thus proven that the phenomenon of "allergy", i.e. the abnormal reaction of a living organism to a particular substance defined as an allergen, has a very major biophysical information side as well as the generally known biochemical and immunological aspect.

Allergy therapy with inverse oscillation of the allergen

The principle of action of bioresonance therapy is exclusively the inverse oscillation (= mirror-image oscillation) of the allergen. This is generated by electronic mirror switching in the BICOM device from the original oscillation of the allergen and is conducted to the patient in several sessions of therapy via cable and electrode.

In the following we present some extracts from the study:

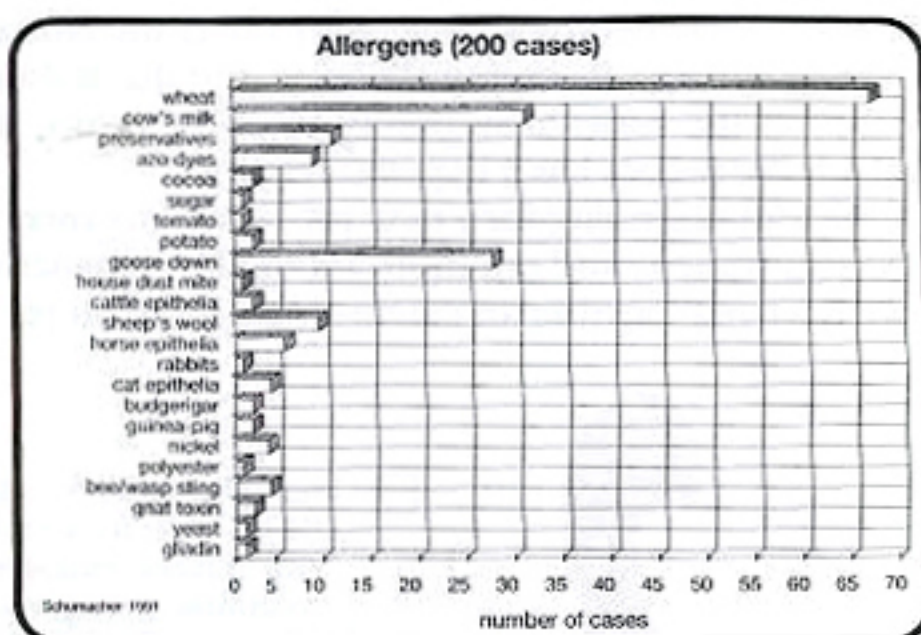

Proof

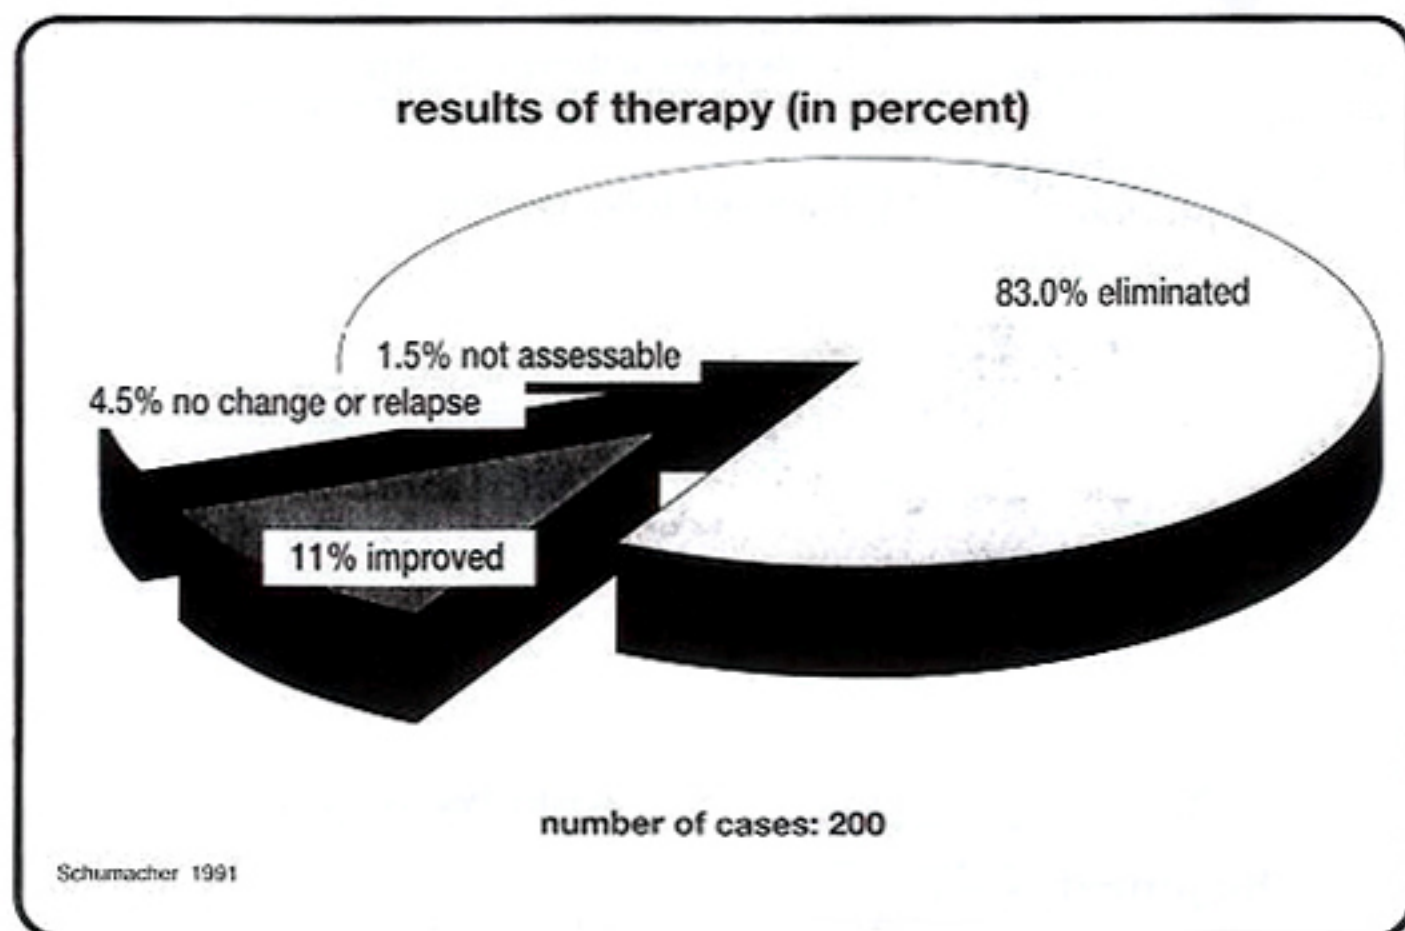

For the individual patient, who is only too well aware of his allergen as the trigger of troublesome to life-threatening symptoms, the fact that he permanently tolerates this substance after therapy without suffering any reaction is an experience bordering on the unbelievable which does not require any further proof.

To make a novel, and in particular such a revolutionary, therapeutic concept credible as a method, there is a need first of all for a larger quantity of statistical material.

The first precise statistical study on the efficacy of biophysical inverse oscillation therapy for allergies has been completed and will shortly be published.

Extract from a study by Dr P. Schumacher, paediatrician, Innsbruck:

After the therapeutic series was completed, each patient was at first routinely re-examined. The final assessment of the results of

therapy was made 4 to 10 months later by the patient himself or his parents in the form of a questionnaire. The few failures in

therapy and relapses are without exception attributable to deficiencies during the therapy phase.
